

Betting on bits

contextual influences on the perception of ‘phonetic categories’

Sarah Hawkins

University of Cambridge

sh110@cam.ac.uk

Issues

- Context and phoneme/word identification
- Structuring a model of speech understanding
 - top-down vs. bottom-up information
 - abstraction vs exemplar representation

We can understand speech
because there's an invariant
acoustic correlate for every
one of Morris' features

Oh yeah? So why doesn't
~~/vab/sound like a name in~~
Lagis and Hawaii and
and Birmingham?

Fine phonetic detail (FPD): random or systematic?

much is systematic & perceptually salient

but does **NOT** help to identify citation form
words or phonemes

Fine phonetic detail indicates:

- position in syllable; syllable structure
- word boundaries
- grammatical status
- places where you can join in a conversation
- discourse function of ‘the same’ words
- other things crucial to a normal conversation
- gross and subtle indexical information

Systematizing fine phonetic detail

- a different way of conceptualizing
 - phonetic and phonological structure (Firthian)
 - the processes of understanding speech
- *Journal of Phonetics* 31(3/4)
especially John Local; Sarah Hawkins
- Hawkins & Smith (2001)
Italian Journal of Linguistics – Riv. de Ling. 13, 99-188
<http://kiri.ling.cam.ac.uk/sarah/pubs.html>

Systematizing fine phonetic detail

– the processes of understanding speech

- *Journal of Phonetics* 31(3/4)

What is a category?

A class or division in a
system of classification

(OED)

Structure of a category

Quality of exemplars

Boundaries

✓
Thrush in summer

✓
Thrush in snow

✗
Sparrow in summer

Ladefoged and Broadbent (1957)

"Please say what this word is:

bit bet bat but

F1 of CARRIER

bet

200-380 Hz

bit

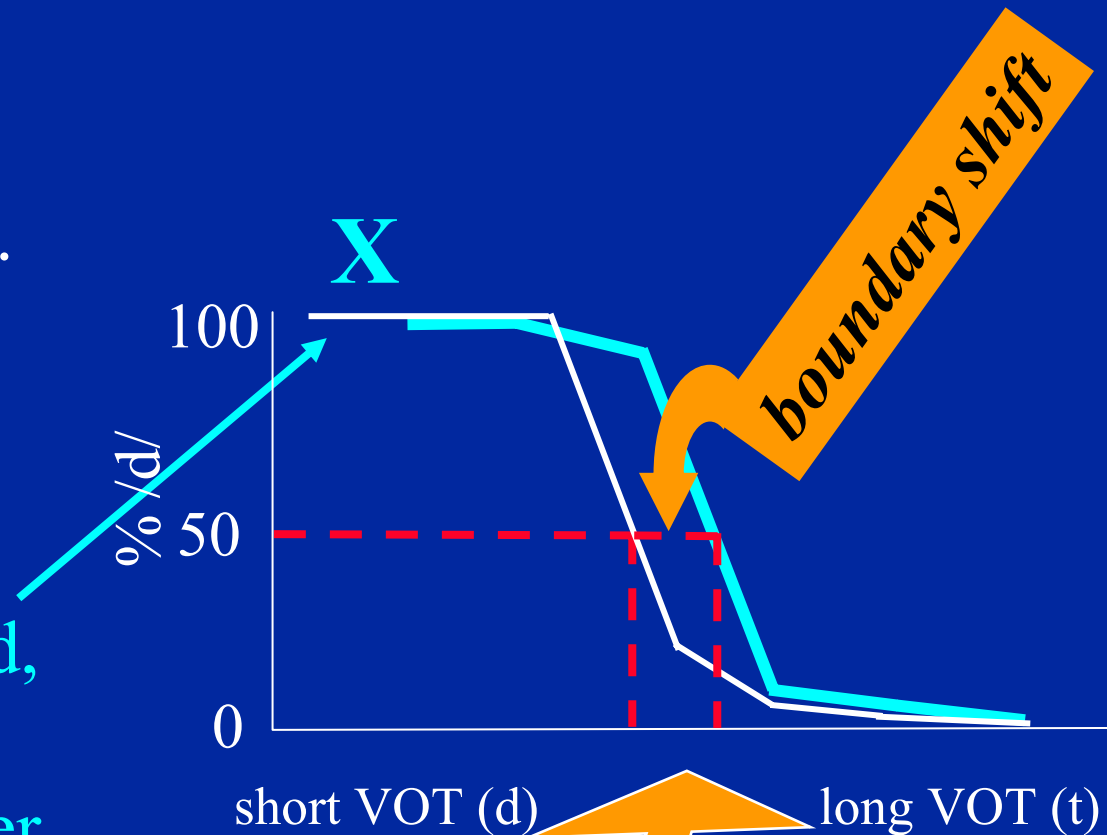

380-660 Hz

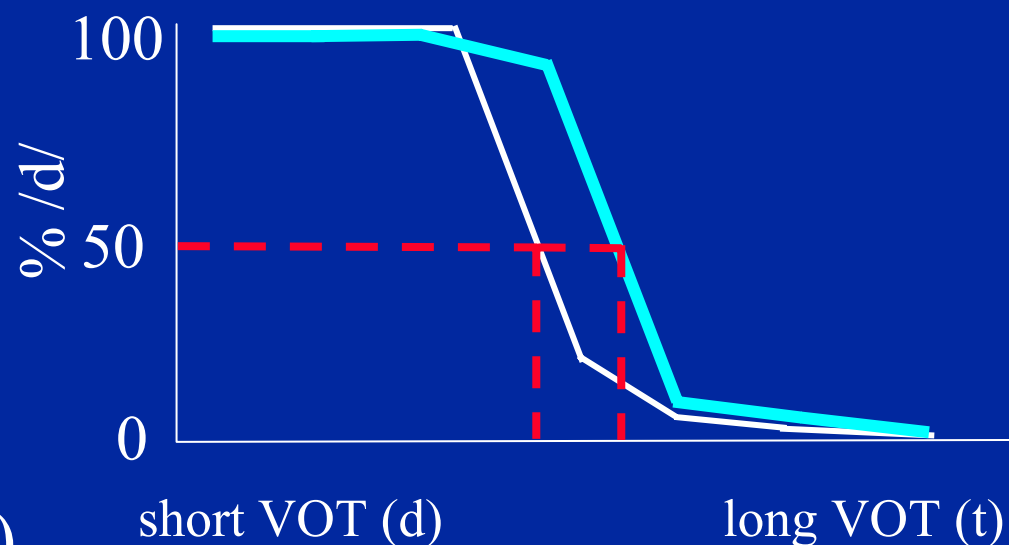

“Range effects” on CP boundary

- identification expt e.g.
- VOT continuum
da.....ta
- when stimuli are removed from one end, the 50% id boundary shifts towards the other

What causes a boundary shift?

- stimulus range
(distribution)
- perceived rate of speech
- lexicality/Ganong
(word~nonword)
- sentence meaning
(if the task is appropriate)

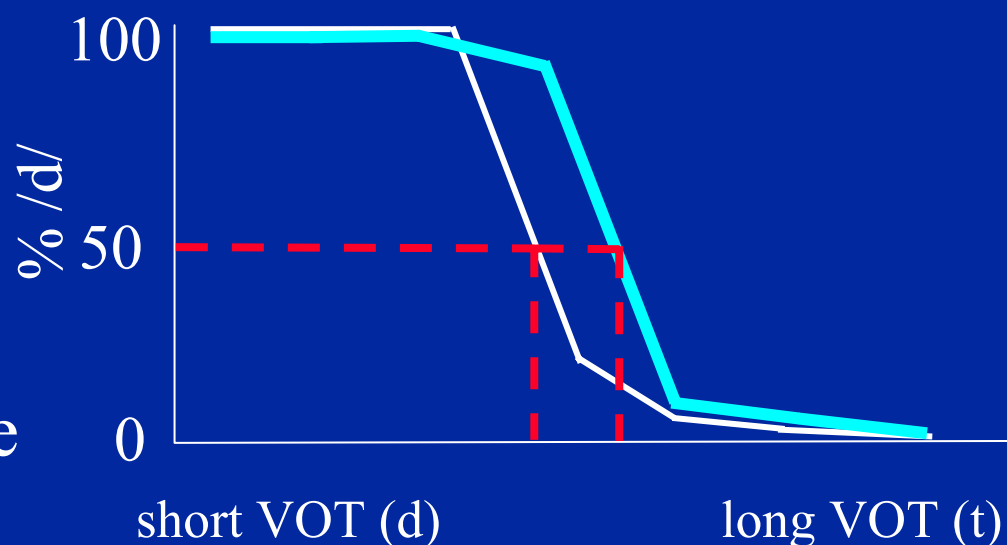

Summerfield (1981) *JEP:HPP* 7, 1074-1095

Ganong (1980) *J. Exp. Psych: HPP* 6, 110-125

Borsky, Shapiro, Tuller (2000) *J. Psycholinguistic Res.* 29, 155-168

What causes a boundary shift?

Perception adjusts to the
distribution of stimuli
&
is more forgiving
about unclear sounds
if the message makes sense

Summerfield (1981) *JEP:HPP* 7, 1074-1095

Ganong (1980) *J. Exp. Psych: HPP* 6, 110-125

Borsky, Shapiro, Tuller (2000) *J. Psycholinguistic Res.* 29, 155-168

CP: category goodness

Much evidence that ‘better’ instances of phonemes exert stronger perceptual effects of many types:

Samuel (P&P 1982 adaptation)

Kuhl (1992 perceptual magnet effect [PME])

And that context affects category goodness

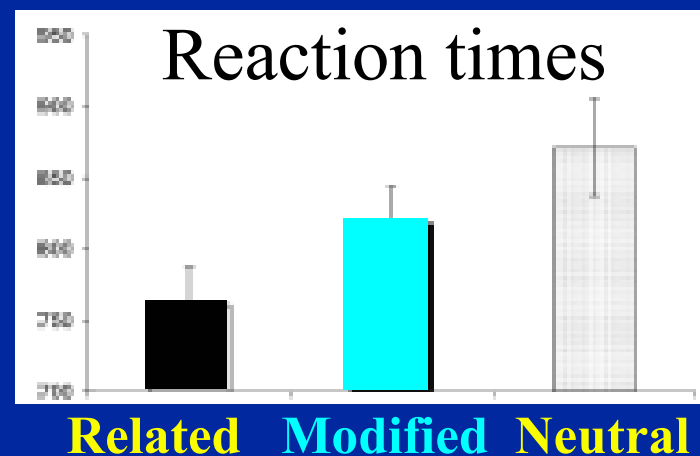

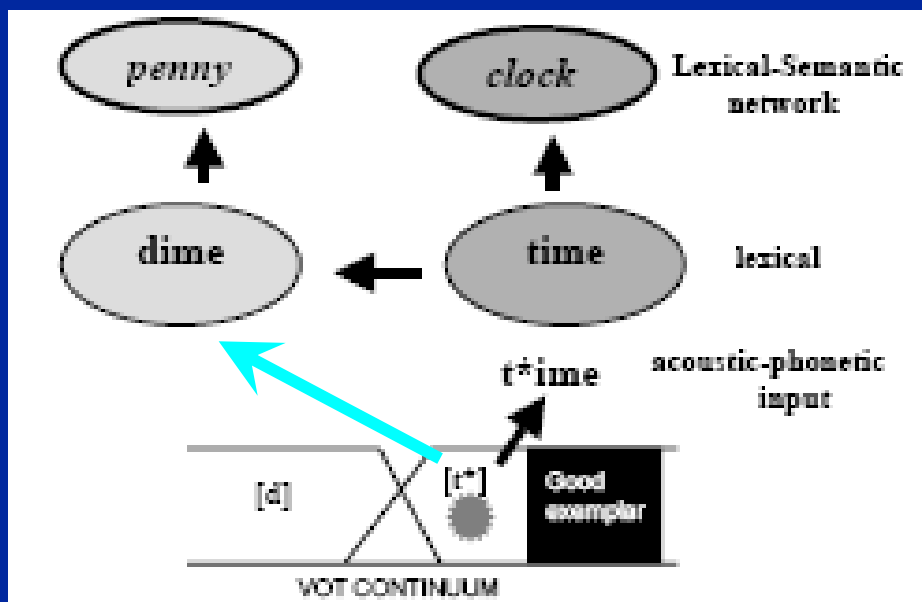

Hawkins & Barrett (ASA 04: PME)

Allen & Miller (P&P 2001: rate and lexicality)

CP: category goodness

Mediated Priming in lexical decision task

A /t/ with a short VOT primes unrelated words via rhymes that have /d/ instead of /t/

t*ime primes penny via dime

Linguistic categories: summary

- Perception adjusts to the distribution of stimuli and is more forgiving about unclear sounds if the message makes sense or the task encourages it
- ‘Units’ are functionally inseparable from ‘context’
- Implication: mental representations of linguistic-phonetic categories are relational and plastic

How might this plasticity occur?

An example

Plasticity of single neurons in the
Primary Auditory Cortex (PAC)

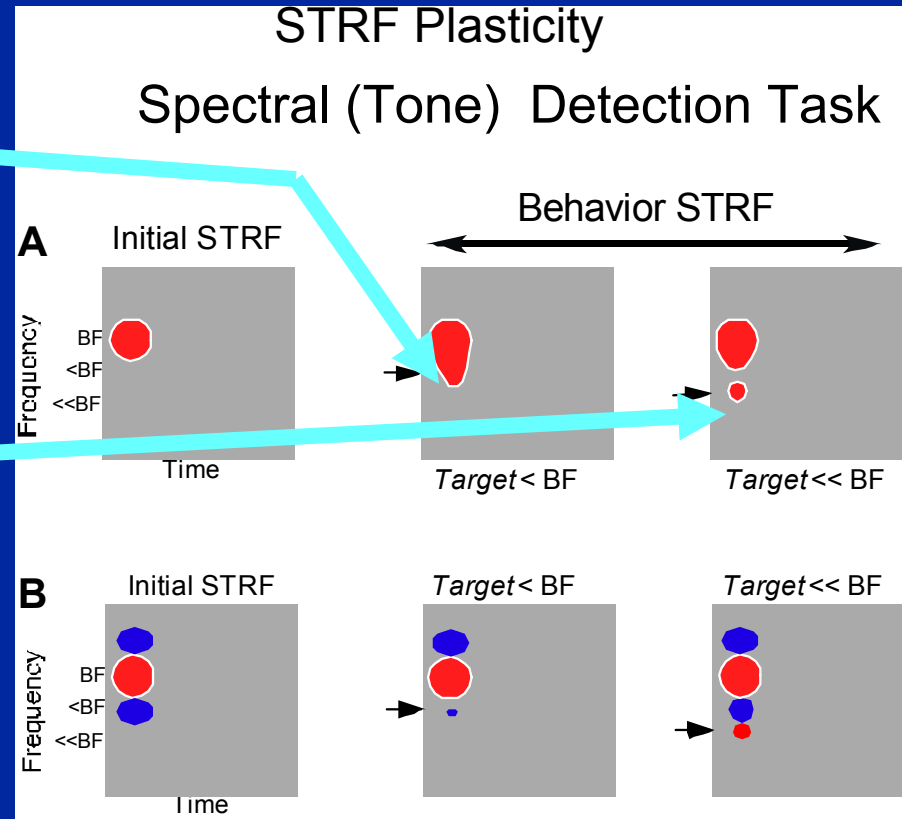

Spectro-temporal receptive fields (STRFs) in PAC

- Recording from single neurons in PAC
- Sensitive to particular frequency ranges and temporal relationships
- Training:
 - broadband noise: **lick**
 - tone (constant frequency sine wave): **don't lick**
- Test: **different tone frequency**

Plasticity of STRFs in PAC

- Shift in excitatory response to tone of similar frequency
- Additional field to yet more different tone
- Only when a response is required: ‘meaning’
- Poorer task performance and weaker plasticity are correlated

● excitatory field BF neuron best freq
● inhibitory field → target freq

Summary: STRF changes in PAC

- Swift (2.5-8 minutes); last several hours
- Reflect
 - sensory content
 - changing behavioral meaning of acoustic stimuli
- Consistent with facts of speech perception
- Similar adaptation/learning probably occurs earlier (lower down) in the auditory pathway

Brain activation for category boundaries

- Many studies: **Superior Temporal Gyrus (STG)** is active when phonetic decisions are made (+ many other areas)
- STG activation does not differ when the decisions are hard (other areas do e.g. **frontal** regions)

Binder *et al.* (2004) *Nat. Neurosci.* 7, 295-301

Blumstein *et al.* (2005) *J. Cog. Neuroscience* 17, 1353-1366

Brain activation for category boundaries: Ganong effect

- STG *is* sensitive to change in category boundary due to lexical status: gift-kift; giss-kiss
- Conclusion: lexical knowledge influences basic phonetic categorization processes

yet also.... simple ba-da continuum

- brain activation differs for category centers & boundaries (adaptation fMRI)

centers: Primary auditory cortex, left parietal

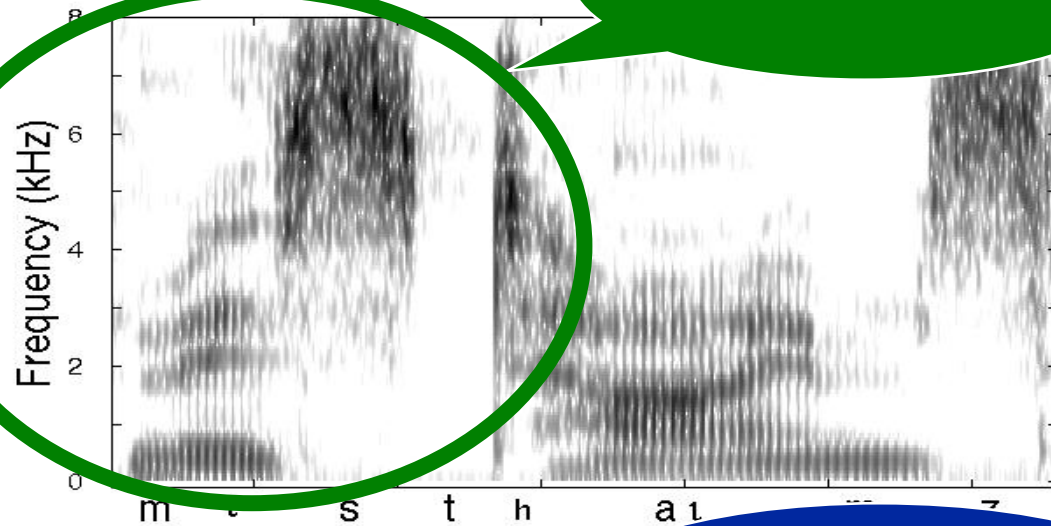

boundaries: left SMG, L middle frontal, R prefrontal, Right cerebellum, anterior cingulate

What does this mean?

- Category boundaries and centers are analyzed in many different parts of the brain:
don't and can't act independently
- **Relationships** in current signal are constantly interpreted from all available evidence:
 - knowledge
 - current sensation (quite detailed)
 - attention

Productive

Unproductive

Fine phonetic detail provides all sorts of information,

not just phonological.

Here, it is grammatical.

Summary

- Brain is ‘opportunistic’: it uses all available information to understand a message
- Fine phonetic detail can be fundamental
- What listeners do with FPD depends on what they are doing at the moment

Modeling phonetic representation

- Phonetic categories can map directly to phonological categories BUT
 - relational, dynamic, self-organizing, (multi-modal), context-sensitive, task-sensitive
- Sound patterns map to meaning via processes that involve complex (embodied?) structures:
 - MULTIPLE UNITS of speech perception
- Top-down and bottom-up information, episodic vs abstract representation, may not be distinguishable in speech communication
